CUYAHOGA COUNTY OCTOBER, 1940 CLEVELAND, CHIC

STATISTICAL SURVEY OF CUYAHOGA COUNTY CORONER'S OFFICE

CORONER, SAMUEL R. GERBER, M.D.

CUYAHOGA COUNTY OCTOBER, 1940 CLEVELAND, OHIO

As Coroner of Cuyahoga County, in addition to the discharge of my usual routine duties incumbent upon me. I have continuously striven, first, to improve the quality of service by the department, second, to encourage the professional staff to do research work along lines that would contribute to the relatively new field of forensic medicine, and third, to contribute to medical and lay knowledge along similar lines myself; to that end, I have contributed analysis of the work of this office from time to time to newspapers to medical literature and other interested publications. The purpose of such action is two fold: First, to keep the public informed of the progress made in the institution they support, second, to further the general knowledge of this branch of science. The latter function is as much a part of the office of Coroner as is the mere static performance of the routine duties. To deny progress by refusing to accept or contribute to it is not only to halt knowledge, but actually to revert to the "horse and buggy" days of practice. This we can prevent by continuously developing and expanding with the march of science.

The Coroner's Office in the progressive parts of the country is no longer comparable to the Coroner's Office at its inception. In some areas, this office has been replaced by the Medical Examiner's System. Though hampered in some degree by antiquated legislative enactments, this and other progressive offices in the country strive to emulate the quality and scope of function of the ideal Medical Examiner's and Coroner's System.

The following report is a statistical survey of the activity of the Cuyahoga County Coroner's Office for the years of 1937, 1938, and 1939, my first three years in office. The data are presented in detail to be available as such to interested parties. It would be highly desirable if such statistical information would be available from all similar offices in the country.

The first two tables in this report classifies, in large categories, all the cases coming to the attention of the Coroner's Office. The next section classifies the types of homicides, suicides, accidents, and miscellaneous deaths. The cases classified as "Natural Causes" are se parated by systems into the type of disease causing death. Beginning with Table #10, there is another section in which is presented, in a detailed manner, the work performed in the laboratory during this period. The last half of the paper is devoted to an analysis of the fatal vehicular accidents for the same period. A detailed explanatory note accompanies that portion of this report.

DR. S.R. GERBER, CORNER

CUYAHOGA COUNTY MORGUE

ANALYSIS OF FATAL VEHICLE ACCIDENTS OF 1937 1938 AND 1939

By

CORONER, SAMUEL S. R. GERBER, M.D.

CLEVELAND, CHIO

ANALYSIS OF FATAL VEHICLE ACCIDENTS OF 1937, 1938 AND 1939

 $B_{\mathbf{y}}$

CORONER, S. R. GERBER, M.D. CUYAHOGA COUNTY MORGUE, CLEVELAND, OHIO

During the years of 1937, 1938 and 1939, 806 cases of human fatality due directly or indirectly to vehicular accidents were seen at the County Morgue. Inasmuch as a fatality resulting from a vehicular accident, with the exception of "Acts of God," entirely appears to be, in the majority of cases, a useless and unnecessary death and because of the wide spread interest in traffic accidents throughout the country stimulated by the National Safety Council, I have tried to analyze all of our cases in order that through some constructive conclusions, these deaths may be avoided. To my knowledge, a detailed analysis such as this does not exist in print.

The accompanying charts contain the raw data for this analysis. From table #I, it can be seen that victims of every age group fare represented from the ages of I to 80 and over. The greatest number of victims are individuals between the ages of 50 and 54 with only slightly fewer in the age group of 20 and 74. The majority of the victims are males who outnumber the females by 4 to 1.

From table #2, it can be seen that, by far, the greatest number of victims are adults. About I in every 8 are children.

In the study of the seemingly complex table #3, it is possible to analyze the occurrence of the fatalities by days of the week and by the time of day the accident occurred. It is to be noted that these accidents occurred practically during any hour of the day or night. The lowest incidence of fatalities occurred be-

tween the hours of 9 and 11 in the morning. The highest incidence occurred between 8 and 9 in the evening. The greatest proportion of deaths occurred in the hours between 6 P.M. and 3 A.M. It is also significant to note that the highest incidence of accidents causing fatalities among children of school age occurred on Friday and Saturday. Those accidents causing deaths occurring on school days, it is to be noted, happened for the most part during the hours of going to and from school, and in the evening.

In table #4, the fatalities, by the day of the week, are more concisely tabulated. From this table, it can be seen that, by far, the greatest number of deaths occurred as the result of accidents on Friday, Saturday and Sunday.

In table #5, we have a very instructive analysis. Here, the fatal accidents are analyzed chiefly according to the type of accident, but also separated into age groups and the hour of the day during which the accident occurred. If we take into consideration pedestrians who were struck by trucks and street-cars, as well as automobiles, the total percentage of all these deaths would be 63. Insofar as school children are concerned, it would appear that the automobile, truck and street-car are chiefly responsible for their death. However, a significant number are killed riding bicycles. Another important factor in the death of adults is the type of accident involving two automobiles or an automobile and a truck, street-car or train. A not-inconsiderable number occur when automobiles struck safety-zones.

From table #6, we have an analysis of the nature of the injuries sustained in the accidents, leading to the death of the individual, and an analysis of the type of accident that resulted in these fatalities. In many of these cases, autopsies were not performed, so the exact nature of the cause of death cannot be fully determined. It can be seen that such cases are classified as "Undetermined internal injuries." There are 197 in this group of 806 cases. Where ascertainable, it can be noted that, by far, the most frequent cause of death in automobile accidents is the fractured skull. Death of this kind occurred in every type of conceivable accident. Very frequently, death occurred from fractured ribs and crushed chest usually following accidents involving two automobiles or an automobile and a pedestrian. Fractured arms and leas resulted chiefly when a pedestrian was injured by an automobile. Fracture of the spine calso occurred frequently. Injuries to the heart occurred in a small number of cases where automobiles struck pedestrians. Fractured pelvic bones appears to be relatively common, chiefly in automobile-pedestrian types of accidents. In a small number of instances, where two automobiles crashed, fires resulted in 2nd and 3rd degree body burns, causing death of these individuals. In a small number of cases, chiefly when the automobile struck a safety-zone, the large blood vessels of the neck were cut with death resulting from secondary hemorrhage. A few unusual types of deaths were encountered, namely, deaths from drowning when automobiles went over an embankment into the water, or in one instance, where an individual stepped out of a car into a puddle of water at the same time touching an electrified wire.

Table #7 is self-explanatory. It can be seen that the

majority of the 625 victims of these vehicular accidents on whom the data is available came from the ranks of the skilled and unskilled labor. The housewives comprise another relatively large group. Business men and women, students and people retired from active work make up a not-inconsiderable group of victims. Professional people, by far, are least numerous among the victims.

In table #8, we have an exceedingly interesting analysis, showing whether the individual who was killed was engaged in regular occupation or not at the time of the accident. Analysis shows that of these individuals, only a very small fraction of the total (37 out of the 806) were engaged in their regular occupation, and these individuals were males. Not a single case of death in females occurred while they were engaged in their regular occupation and not all of the victims were housewives.

From table #9, in the majority of the cases, the driver of an automobile had disregarded the law in one or more ways. Death, in small number of cases, was due to utter carelessness; the remainder, to negligence.

In table #10, we have a similar analysis pertaining to the pedestrians who were killed and what they were doing at the time of their death. From this, it can be seen that negligence or carelessness on the part of the pedestrian contributed materially to his death.

From tables #II, I2 and I3, we have an analysis of the drivers of cars, other occupants and pedestrians according to their physical condition at the time of their death. It can be seen that the majority of the victims had no physical defect and that a large proportion of the adults were under the influence of liquor.

In table #14, we have an analysis of the accidents in relation to the condition of the road on which the accident occurred and from this it can be seen that, by far, the greatest number of accidents occurred on well-paved dry roads.

Analysis of the tables #15 and 16 shows that the majority of the accidents occurred under average lighting condition and in good weather. In a very small number of cases could the accidents only be definitely attributed to darkness, poor lighting conditions or inclement weather.

SUMMARY_AND_CONCLUSION

To summarize, it would appear that, by far, the greatest number of deaths occurred in healthy individuals, chiefly adults who were not in their regular occupation at the time of their death. Most of these deaths occurred in the evening and early morning hours and during the week-end. The accidents resulting in these deaths occurred when the weather conditions were good and on roads that were paved, dry and under average lighting conditions. At the time of the accident, it was also shown that most of the individuals were either careless or negligent. In only a small percentage of the cases, could death be attributed to accidents that were entirely unavoidable. In the majority of cases the injuries causing death were severe, most frequently fractured skulls.

In regard to the children of school age it is to be emphasized that during the hours of school, protection is afforded these children. Some of the accidents occurred in the hours during which they travel to and from school. The majority, however, oc-

curred in vacation periods, chiefly over the week-ends and in the evenings.

From this, it can be concluded that in the majority of instances, the death of the individual is at least contributed to or caused by his own fault during the period when he is at leisure and his caution is relaxed.

If we take into consideration that were it not due to extreme caution of many other drivers of vehicles and other pedestrians, the total number of vehicular deaths would probably be much greater. As it is, there are two possible procedures we may use, whereby the number of fatalities may be materially reduced. One is education of the individuals to correct their faults or carelessness, and the other, emphasizing caution on part of both drivers of vehicles and of pedestrians.
